

Pointer searcher, which stores words in alphabetical order.
This program gives capital words more precedence.

Tokenizer structure, to store the number of tokens and the tokens found in a dynamically growing array.

Few macro functions to check whether the string is correctly entered and is 'legal'

checkWork() : If the string does not contain any letters then its invalid.
checkFirst() : if the first char in string is not alphabet, then skip it. makes the use of strtok() easier and better.

reWrite() : Whenever there are consecutive delims, rewrite string after deleting one of the delims.

findDelim() : finds delim, recursively finds another delim when consecutive.

createTokens() : creates tokens dynamically.

sortTokens() : sort tokens using strcmp search

killErr() : Free all allocated memory.

Please enter your string in " " (double quotes). or not, your wish.
